# Integer Codes Correcting Burst and Random Asymmetric Errors within a Byte 

Aleksandar Radonjic and Vladimir Vujicic

#### Abstract

In most communication networks, error probabilities $\mathbf{1 \rightarrow 0} \mathbf{0}$ and $\mathbf{0} \rightarrow \mathbf{1}$ are equally likely to occur. However, in some optical networks, such as local and access networks, this is not the case. In these networks, the number of received photons never exceeds the number of transmitted ones. Hence, if the receiver operates correctly, only $1 \rightarrow 0$ errors can occur. Motivated by this fact, in this paper, we present a class of integer codes capable of correcting burst and random asymmetric $(1 \rightarrow 0)$ errors within a $b$-bit byte. Unlike classical codes, the proposed codes are defined over the ring of integers modulo $2^{b}-1$. As a result, they have the potential to be implemented in software without any hardware assist.

 Keywords: Integer codes, error correction, asymmetric errors, optical networks.
## 1. Introduction

Most classes of codes have been designed for use on symmetric channels, where $0 \rightarrow 1$ and $1 \rightarrow 0$ errors occur with equal probability. In some practical systems, however, the probability of $0 \rightarrow 1$ errors is extremely small. One such example are optical networks without optical amplifiers (ONWOAs) (e.g. local and access networks) [1]. In these networks, the number of received photons never exceed the number of sent ones [2], [3]. Hence, if the receiver operates correctly, only asymmetric $(1 \rightarrow 0)$ errors may occur. These include random errors as well as bursts of length up to 8 bits [4], [5], [6], [7].

Although this fact is known for decades, there has been very little work on codes for ONWOAs. Some classes of burst asymmetric codes were presented in [8], [9], but without any information regarding their implementation. The same holds for [10], [11], where the authors proposed two classes of codes capable of correcting random and byte asymmetric errors, respectively. Unlike the above-mentioned works, in [13] we have presented a class of codes that is specially designed for use in ONWOAs. The main advantage of these codes is the ability to exploit high computing power of the network nodes (PCs, servers, routers, switches, OLT/ONU units, etc.) [1]. This has been achieved by using integer and lookup table (LUT) operations, which are supported by all processors. Unfortunately, in terms of error correction, these codes were quite weaker than [8], [9], [10], [11]. More precisely, they were able to correct spotty byte asymmetric errors, unlike [8], [9], [10], [11] which are designed to correct multiple asymmetric errors within a byte or codeword.

In this paper, we present a class of codes that significantly outperforms the codes proposed in [13]. Unlike them, the codes presented in this paper can correct two types of errors within a $b$ bit byte: burst asymmetric errors up to $l(<b)$ bits ( $l / b$ BA errors) and random asymmetric errors up to $t(<l)$ bits ( $t / b$ RA errors). The only penalty for this improved performance is a slight increase in memory requirements. On the other hand, the proposed codes retain all the desirable properties of [13] including systematic structure, simple encoding/decoding algorithm and fast error control procedure based on table lookups.

The organization of this paper is as follows: Section 2 deals with the construction of integer codes capable of correcting $l / b \mathrm{BA}$ and $t / b$ RA errors (integer $\left(\mathrm{B}_{l} \mathrm{AEC} / \mathrm{R}_{t} \mathrm{AEC}\right)_{b}$ codes). The implementation strategy and theoretical decoding throughputs for these codes are described and evaluated in Section 3. In Section 4 the proposed codes are compared with the existing codes of similar properties. Finally, Section 5 concludes the paper. For ease of reading, a list of notations is given in Table 1.

Table 1. Notations Used in This Paper.

| Symbol | Meaning |
| :---: | :---: |
| $B_{i}$ | Integer value of the $i$-th $b$-bit data byte at the sender side |
| $C_{\mathrm{B}}$ | Integer value of the $b$-bit check-byte at the sender side |
| $\hat{B}_{i}$ | Integer value of the received $i$-th $b$-bit data byte |
| $\hat{C}_{\mathrm{B}}$ | Integer value of the received $b$-bit check-byte |
| $C_{\hat{\mathrm{B}}}$ | Integer value of the $b$-bit check-byte at the receiver side |

## 2. Codes Construction

## A. Encoding and Decoding Procedures

Let $Z_{2^{b}-1}=\left\{0,1, \ldots, 2^{b}-2\right\}$ be the ring of integers modulo $2^{b}-1$, and let $C_{i} \in Z_{2^{b}-1} \backslash\{0,1\}$, where $1 \leq i \leq k$. In addition, let us assume that the encoder/decoder uses a $\operatorname{LUT}_{1}$ to store the coefficients $C_{i} \in Z_{2^{b}-1} \backslash\{0,1\}$. In that case, the encoder will generate the check-byte $C_{\mathrm{B}}$ by using the following operations:

$$
\begin{equation*}
C_{\mathrm{B}}=\left[C_{1} \cdot B_{1}+\cdots+C_{k} \cdot B_{k}\right]\left(\bmod 2^{b}-1\right)=\sum_{i=1}^{k} C_{i} \cdot B_{i}\left(\bmod 2^{b}-1\right) \tag{1}
\end{equation*}
$$

At the receiver, the decoder will perform the same calculation

$$
\begin{equation*}
C_{\hat{\mathrm{B}}}=\left[C_{1} \cdot \hat{B}_{1}+\cdots+C_{k} \cdot \hat{B}_{k}\right]\left(\bmod 2^{b}-1\right)=\sum_{i=1}^{k} C_{i} \cdot \hat{B}_{i}\left(\bmod 2^{b}-1\right) \tag{2}
\end{equation*}
$$

after which the syndrome $S$ will be formed

$$
\begin{equation*}
S=\left[C_{\hat{\mathrm{B}}}-\hat{C}_{\mathrm{B}}\right]\left(\bmod 2^{b}-1\right) \tag{3}
\end{equation*}
$$

Obviously, when $S \neq 0$, the codeword is corrupted by one or more errors.

## B. Necessary and Sufficient Conditions

In order to be able to correct all $l / b$ BA and $t / b$ RA errors, the decoder must know which nonzero values of $S$ correspond to these errors. However, before we move to the mathematical details, let us observe that $t / b$ RA errors spaced less than $l$ bits (short $t / b$ RA errors) can be treated as $l / b$ BA errors. Hence, in addition to $l / b$ BA errors, we need to consider only $t / b$ RA errors that are spaced $d(l<d<b)$ bits apart (long $t / b$ RA errors) (Fig. 1).

a)

Fig. 1. (a) Short $t / b$ RA errors and (b) long $t / b$ RA errors.

Now we can give two definitions, the first of which stems from our previous work [12].
Definition 1. Let $e_{1}=\{1\}$ and $e_{w}=\left\{2^{w-1}+1,2^{w-1}+3, \ldots, 2^{w}-1\right\}$ be the sets of odd integers, and let $l$ be an integer such that $2 \leq w \leq l<b$. Then, the set of syndromes corresponding to $l / b$ BA errors is defined as

$$
\begin{equation*}
\varepsilon_{1}=s_{1} \cup s_{2} \tag{4}
\end{equation*}
$$

where
$s_{1}=\left\{\bigcup_{m=1}^{l}\left(2^{r} \cdot e_{m}\right)\left(\bmod 2^{b}-1\right): 0 \leq r \leq b-m\right\}$
$s_{2}=\left\{\bigcup_{m=1}^{l} \bigcup_{i=1}^{k}\left(-C_{i} \cdot 2^{n} \cdot e_{m}\right)\left(\bmod 2^{b}-1\right): 0 \leq r \leq b-m\right\}$
Definition 2. Let $f_{2}=\left\{2^{s}+2^{z}\right\}$ and $f_{v}=\left\{2^{s}+2^{x_{1}}+2^{x_{2}}+\cdots+2^{x_{v-2}}+2^{z}\right\}$ be the sets of integers, where $3 \leq v<l<b, 0 \leq s<x_{1}<x_{2}<\ldots<x_{v-2}<z$ and $s+l \leq z \leq b-1$. Then, the set of syndromes corresponding to long $t / b$ RA errors is defined as
$\varepsilon_{2}=s_{3} \cup s_{4}$
where

$$
\begin{align*}
& s_{3}=\left\{\bigcup_{n=2}^{t}\left(f_{n}\right)\left(\bmod 2^{b}-1\right): 2 \leq t<l\right\}  \tag{8}\\
& s_{4}=\left\{\bigcup_{n=2}^{t} \bigcup_{i=1}^{k}\left(-C_{i} \cdot f_{n}\right)\left(\bmod 2^{b}-1\right): 2 \leq t<l\right\} \tag{9}
\end{align*}
$$

Although the expressions (1)-(9) provide a theoretical basis for the construction of $(k b+b$, $k b)$ integer $\left(\mathrm{B}_{l} \mathrm{AEC} / \mathrm{R}_{t} \mathrm{AEC}\right)_{b}$ codes, they do not give the explicit information about the number of nonzero syndromes. Hence, we need the following theorem.

Theorem 1. The codes defined by (1)-(3) can correct all $l / b B A$ and $t / b$ RA errors iff there exist $k$ mutually different coefficients $C_{i} \in Z_{2^{b}-1} \backslash\{0,1\}$ such that

1. $\left|\varepsilon_{1}\right|=(k+1) \cdot\left[2^{l-1} \cdot(b-l+2)-1\right]$
2. $\left|\varepsilon_{2}\right|=(k+1) \cdot \sum_{i=0}^{b-l-1} \sum_{j=2}^{t}(b-l-i) \cdot\binom{l+i-1}{j-2}$
3. $\varepsilon_{1} \cap \varepsilon_{2}=\varnothing$
where $|A|$ denotes the cardinality of $A$, and $A \cap B$ the intersection of $A$ and $B$.
Proof. Condition 1 of this theorem says that $l / b$ BA errors generate $(k+1) \cdot\left[2^{l-1} \cdot(b-l+2)-1\right]$ syndromes that are nonzero. To prove this, observe that the set $s_{1}$ can be expressed as
$s_{1}=\bigcup_{m=1}^{l} a_{m}$
where
$a_{1}=\left\{(1) \cdot 2^{r}\left(\bmod 2^{b}-1\right): \quad r=0,1, \ldots, b-1\right\}$
$a_{2}=\left\{(3) \cdot 2^{r}\left(\bmod 2^{b}-1\right): \quad r=0,1, \ldots, b-2\right\}$
$a_{l}=\left\{\left(2^{l-1}+1,2^{l-1}+3,2^{l-1}+5, \ldots, 2^{l}-1\right) \cdot 2^{r}\left(\bmod 2^{b}-1\right): r=0,1, \ldots, b-l\right\}$
Consequently, we can write
$\left|s_{1}\right|=\sum_{m=1}^{l}\left|a_{m}\right|=b+\sum_{h=2}^{l} 2^{h-2} \cdot(b-h+1)$.
To calculate the sum we can use equalities
$\sum_{j=1}^{l-1} x^{j}=\frac{x^{l}-1}{x-1}$
$\sum_{j=1}^{l-1} j \cdot x=x \cdot \frac{1-x^{l-1}}{(1-x)^{2}}-\frac{(l-1) \cdot x^{l}}{1-x}$
wherefrom it follows that
$\left|s_{1}\right|=b+(b+1) \cdot\left(2^{l-1}-1\right)-l \cdot 2^{l-1}+2^{l-1}=2^{l-1} \cdot(b-l+2)-1$.
On the other hand, from (5) and (6) we see that the set $s_{2}$ can be expressed as
$s_{2}=\bigcup_{i=1}^{k} b_{i}$
where
$b_{1}=\left\{\left(-C_{1} \cdot s_{1}\right)\left(\bmod 2^{b}-1\right)\right\}$
$b_{2}=\left\{\left(-C_{2} \cdot s_{1}\right)\left(\bmod 2^{b}-1\right)\right\}$
$b_{k}=\left\{\left(-C_{k} \cdot s_{1}\right)\left(\bmod 2^{b}-1\right)\right\}$
From this it is easy to conclude that the syndromes caused by $l / b$ BA errors will be different and not equal to zero iff there exist $k$ mutually different coefficients $C_{i} \in Z_{2^{b}-1} \backslash\{0,1\}$ such that
$s_{1} \cap s_{2}=s_{1} \cap b_{1} \cap b_{2} \cap \cdots \cap b_{k}=\varnothing$
$\left|s_{1}\right|=\left|b_{1}\right|=\left|b_{2}\right|=\cdots=\left|b_{k}\right|=2^{l-1} \cdot(b-l+2)-1$.
In that and only in that case, the set $\varepsilon_{1}$ will have
$\left|\varepsilon_{1}\right|=\left|s_{1}\right|+\left|s_{2}\right|=\left|s_{1}\right|+k \cdot\left|s_{1}\right|=(k+1) \cdot\left[2^{l-1} \cdot(b-l+2)-1\right]$
nonzero elements. In a similar way Condition 2 says that long $t / b$ RA errors generate $(k+1) \cdot \sum_{i=0}^{b-l-1} \sum_{j=2}^{t}(b-l-i) \cdot\binom{l+i-1}{j-2}$ syndromes that are nonzero. To prove this, note that the set $s_{3}$ can be expressed as
$S_{3}=\bigcup_{u=0}^{b-l-1} c_{u}$
where
$c_{0}=\{(2^{s}+\underbrace{2^{e}+2^{f}+\cdots+2^{p}}_{t-2 \text { addends }}+2^{s+l})\left(\bmod 2^{b}-1\right): s=0,1, \ldots, b-l-1\}$
$c_{1}=\{(2^{s}+\underbrace{2^{e}+2^{f}+\cdots+2^{p}+2^{s+l+1}}_{t-2 \text { addend }})\left(\bmod 2^{b}-1\right): s=0,1, \ldots, b-l-2\}$
$c_{b-l-1}=\{(2^{s}+\underbrace{2^{e}+2^{f}+\cdots+2^{p}}_{-2 \text { addends }}+2^{s+b-1})\left(\bmod 2^{b}-1\right): s=0\}$
and $s<e<f<\ldots<p<s+l+u$ for any $u=0,1, \ldots, b-l-1$. Consequently, we can write
$\left|c_{0}\right|=(b-l) \cdot\binom{l-1}{t-2}$
$\left|c_{1}\right|=(b-l-1) \cdot\binom{l}{t-2}$
$\left|c_{b-l-1}\right|=1 \cdot\binom{b-2}{t-2}$
wherefrom it follows that
$\left|s_{3}\right|=\sum_{u=0}^{b-l-1}\left|c_{u}\right|=\sum_{i=0}^{b-l-1} \sum_{j=2}^{t}(b-l-i) \cdot\binom{l+i-1}{j-2}$.
On the other hand, from (8) and (9) we see that the set $s_{4}$ can be expressed as
$s_{4}=\bigcup_{i=1}^{k} d_{i}$
where

$$
\begin{gathered}
d_{1}=\left\{\left(-C_{1} \cdot s_{3}\right)\left(\bmod 2^{b}-1\right)\right\} \\
d_{2}=\left\{\left(-C_{2} \cdot s_{3}\right)\left(\bmod 2^{b}-1\right)\right\} \\
\vdots \\
d_{k}=\left\{\left(-C_{k} \cdot s_{3}\right)\left(\bmod 2^{b}-1\right)\right\}
\end{gathered}
$$

Obviously, the syndromes caused by long $t / b$ RA errors will be different and not equal to zero iff there exist $k$ mutually different coefficients $C_{i} \in Z_{2^{b}-1} \backslash\{0,1\}$ such that

$$
\begin{aligned}
& s_{3} \cap s_{4}=s_{3} \cap d_{1} \cap d_{2} \cap \cdots \cap d_{k}=\varnothing \\
& \left|s_{3}\right|=\left|d_{1}\right|=\left|d_{2}\right|=\cdots=\left|d_{k}\right|=\sum_{i=0}^{b-l-1} \sum_{j=2}^{t}(b-l-i) \cdot\binom{l+i-1}{j-2}
\end{aligned}
$$

Only in that case the set $\varepsilon_{2}$ will have

$$
\left|\varepsilon_{2}\right|=\left|s_{3}\right|+\left|s_{4}\right|=\left|s_{3}\right|+k \cdot\left|s_{3}\right|=(k+1) \cdot \sum_{i=0}^{b-l-1} \sum_{j=2}^{t}(b-l-i) \cdot\binom{l+i-1}{j-2}
$$

nonzero elements. Finally, Condition 3 is a necessary condition for distinguishing $l / b$ BA errors from long $t / b$ RA errors. So, $(k b+b, k b)$ integer $\left(\mathrm{B}_{l} \mathrm{AEC} / \mathrm{R}_{t} \mathrm{AEC}\right)_{b}$ codes must satisfy all the conditions 1 to 3 . Conversely, if the codes satisfy conditions 1 to 3 , then we can distinguish $l / b$ BA errors from long $t / b$ RA errors. We can also correct all $l / b$ BA and $t / b$ RA errors. Therefore, these codes are $(k b+b, k b)$ integer $\left(\mathrm{B}_{l} \mathrm{AEC} / \mathrm{R}_{t} \mathrm{AEC}\right)_{b}$ codes.

From a practical point of view it is sufficient to use the codes capable of correcting up to three RA errors within a $b$-bit byte. Such a choice is completely in agreement with the theory [6] as well as with experimental results [4], [5], [6], [7]. In addition, it significantly reduces the size of the syndrome table which is used during the error correction process.

Theorem 2. Let $t=2,3$ and let $\xi_{l, t, b, k}=\varepsilon_{1} \cup \varepsilon_{2}$ be the error set for ( $k b+b, k b$ ) integer $\left(B_{l} A E C / R_{t} A E C\right)_{b}$ codes. Then,

$$
\begin{aligned}
& \left|\xi_{l, 2, b, k}\right|=\left|\varepsilon_{1}\right|+\left|\varepsilon_{2}\right|=\left[2^{l-1} \cdot(b-l+2)-1+\frac{(b-l)^{2}+b-l}{2}\right] \cdot(k+1) \\
& \left|\xi_{l, 3, b, k}\right|=\left|\varepsilon_{1}\right|+\left|\varepsilon_{2}\right|=\left[2^{l-1} \cdot(b-l+2)-1+\frac{(b-l)^{2}+b-l}{2} \cdot b\right] \cdot(k+1)-\left[\frac{2 \cdot(b-l)^{3}+3 \cdot(b-l)^{2}+b-l}{6}\right] \cdot(k+1) .
\end{aligned}
$$

Proof. This theorem follows directly from Theorem 1.

To illustrate the applicability of Theorem 1, we show results of a computer-search for the codes with parameters $b=32,2 \leq t \leq 3$ and $8 \leq l \leq 9$ (Appendix A). The software used for the search is written in MATLAB (Appendix B). Its aim is to find the first 128 coefficients $C_{i} \in Z_{2^{32}-1} \backslash\{0,1\}$ that satisfy the conditions of Theorem 1.

## C. Error Control Procedure

Suppose that the decoder uses the syndrome table $\left(\operatorname{LUT}_{2}\right)$ with $\left|\xi_{l, t, b, k}\right|$ entries, where each entry has $2 b+\left\lceil\log _{2}(k+1)\right\rceil$ bits. Unlike the $\mathrm{LUT}_{1}$, which stores the coefficients $C_{\mathrm{i}}$, this table is generated using (4)-(9). Its aim is to describe the relationship between the nonzero syndrome (element of the set $\xi_{l, t, b, k}$ ), error location (i) and error vector (e) (Fig, 2).

Fig. 2. Bit-width of one $\mathrm{LUT}_{2}$ entry.
Bearing this in mind, it is easy to see that the main task of the decoder is to find the entry where the first $b$ bits match that of the syndrome $S$. For that purpose, the decoder must perform a series of table lookups, where each lookup includes a comparison of two $b$-bit vectors (similar to routing [14]). In the end, after $n_{\text {TL }}$ table lookups, the decoder will declare failure ( $S \notin \xi_{l, t, b, k}$ ) or execute ( $S \in \xi_{l, t, b, k}$ ) one of the following operations:

- for l/b BA errors within the check-byte
$C_{B}=\left[\hat{C}_{\mathrm{B}}+e\right]\left(\bmod 2^{b}-1\right)$;
$e=\left[2^{r} \cdot e_{m}\right]\left(\bmod 2^{b}-1\right), 0 \leq r \leq b-m, 1 \leq m \leq l<b ;$
- for l/b BA errors within the $i$-th data byte
$B_{i}=\left[\hat{B}_{i}+e\right]\left(\bmod 2^{b}-1\right), 1 \leq i \leq k ;$
$e=\left[2^{r} \cdot e_{m}\right]\left(\bmod 2^{b}-1\right), 0 \leq r \leq b-m, 1 \leq m \leq l<b$;
- for t/b RA errors within the check-byte
$C_{\mathrm{B}}=\left[\hat{C}_{\mathrm{B}}+e\right]\left(\bmod 2^{b}-1\right)$;
$e=\left[f_{n}\right]\left(\bmod 2^{b}-1\right), 2 \leq n \leq t<b ;$
- for t/b RA errors within the $i$-th data byte
$B_{i}=\left[\hat{B}_{i}+e\right]\left(\bmod 2^{b}-1\right), 1 \leq i \leq k ;$
$e=\left[f_{n}\right]\left(\bmod 2^{b}-1\right), 2 \leq n \leq t<b ;$

Although error correction procedure is very simple, it is clear that its efficiency depends on the number of compares. For this reason it is very important that the elements of $\xi_{l, t, b, k}$ are sorted in increasing order. In that case it is possible to use binary search algorithm, which requires $n_{\mathrm{TL}}$ table lookups $\left(1 \leq n_{\mathrm{TL}} \leq\left\lfloor\log _{2}\left|\xi_{l, t, b, k}\right|\right\rfloor+2\right)$ [15].

Example 1. Let $b=10, t=2, l=3, k=2, C_{1}=3$ and $C_{2}=13$. According to Lemma 1, the $\operatorname{LUT}_{2}$ will have $\left|\xi_{3,2,10,2}\right|=189$ entries (Table 2). Given this, let us assume that we want to transmit 20 bits of data, $\mathrm{D}=10111000000111010011$. In that case, after calculating

$$
C_{\mathrm{B}}=\left[C_{1} \cdot B_{1}+C_{2} \cdot B_{2}\right]\left(\bmod 2^{b}-1\right)=[2208+6071](\bmod 1023)=95
$$

the codeword $C_{\mathrm{w}}=101110000001110100110001011111$ will have 30 bits.

Table 2. The Syndrome Table $\left(\mathrm{LUT}_{2}\right)$ for $(30,20)$ Integer $\left(\mathrm{B}_{3} \mathrm{AEC} / \mathrm{R}_{2} \mathrm{AEC}\right)_{10}$ Decoder.

| 48 | 160 | 3 | 160 | 96 | 505 | 2 | 512 | 144 | 825 | 1 | 66 |  |  |  |  |

Scenario 1 ( $l / b$ BA error): Let us assume that during data transmission an error on the 3rd, 4th and 5 th bit has occurred ( $\left.\hat{C}_{\mathrm{w}}=10 \underline{0000000001110100110001011111}\right)$. After calculating
$C_{\hat{\mathrm{B}}}=\left[C_{1} \cdot \hat{B}_{1}+C_{2} \cdot \hat{B}_{2}\right]\left(\bmod 2^{b}-1\right)=[1536+6071](\bmod 1023)=446$
$S=\left[C_{\hat{\mathrm{B}}}-\hat{C}_{\mathrm{B}}\right]\left(\bmod 2^{b}-1\right)=[446-95](\bmod 1023)=351$
the decoder will check whether the value $S=351$ belongs to the set $\xi_{3,2,10,2}$ (Table 2). After completing this task, it will perform error correction by using
$B_{1}=\left[\hat{B}_{1}+e\right]\left(\bmod 2^{b}-1\right)=[512+224](\bmod 1023)=736$.
Scenario 2 ( $t / b$ RA error): Suppose that during data transmission an error on the 12th and 19th bit has occurred ( $\hat{C}_{\mathrm{w}}=10111000000 \underline{0} 110100 \underline{0} 10001011111$ ). In that case, after calculating $C_{\hat{\mathrm{B}}}=\left[C_{1} \cdot \hat{B}_{1}+C_{2} \cdot \hat{B}_{2}\right]\left(\bmod 2^{b}-1\right)=[2208+2717](\bmod 1023)=833$
$S=\left[C_{\hat{\mathrm{B}}}-\hat{C}_{\mathrm{B}}\right]\left(\bmod 2^{b}-1\right)=[833-95](\bmod 1023)=738$
the decoder will conclude that the value $S=738$ indicates an error within the second byte (Table 2). On the basis of this information it will perform the efror correcting procedure by using $B_{2}=\left[\hat{B}_{2}+e\right]\left(\bmod 2^{b}-1\right)=[209+258](\bmod 1023)=467$.

## 3. Implementation Strategy and Theoretical Decoding Throughputs

An important feature of ONWOAs, which is already mentioned, refers to the architecture of the network nodes. Namely, regardless of its role, each network node (PC, server, router, switch, ONU unit, etc.) [1] is equipped with a processor (general purpose or network processor) that is optimized for integer and LUT operations [16], [17]. Thus, it is interesting to investigate which of the proposed codes have the potential to be implemented on existing network hardware.

Without loss of generality, let us suppose that all network nodes are equipped with quadcore processors (Fig. 3) having the following specifications [17], [18]:

1) clock rate. $\mathrm{C}_{\mathrm{R}}=3.5 \cdot 10^{9} \mathrm{~Hz}$,
2) integer addition/subtraction operation: 1 cycle latency,
3) integer multiplication operation: 3 cycles latency,
4) 128-bit shift operation: 1 cycle latency,
5) modulo reduction operation: 1 cycle latency,
6) comparison operation: 1 cycle latency,
7) access to the L1 cache ( 32 KB per core): 4 cycles latency,
8) access to the L 2 cache ( 256 KB per core): 11 cycles latency,
9) access to the L3 cache ( 16 MB shared): 28 cycles latency.

Fig. 3. Block diagram of a quad-core processor.
Table 3. Memory Requirements for Some $\left(\mathrm{B}_{l} \mathrm{AEC} / \mathrm{R}_{3} \mathrm{AEC}\right)_{32}$ Codes.

| Code | $l$ | Memory <br> Requirements <br> for Storing the <br> Coefficients $C_{i}$ | Memory <br> Requirements <br> for Storing the <br> Syndrome Table | \# of Table <br> Lookups |
| :---: | :---: | :---: | :---: | :---: |
| $(1056,1024)$ | 8 | $4 \times 128 \mathrm{~B}$ | 2.32 MB | $1 \leq \mathrm{n}_{\mathrm{TL}} \leq 20$ |
| $(1056,1024)$ | 9 | $4 \times 128 \mathrm{~B}$ | 3.15 MB | $1 \leq \mathrm{n}_{\mathrm{TL}} \leq 20$ |
| $(2080,2048)$ | 8 | $4 \times 256 \mathrm{~B}$ | 4.63 MB | $1 \leq \mathrm{n}_{\mathrm{TL}} \leq 20$ |
| $(2080,2048)$ | 9 | $4 \times 256 \mathrm{~B}$ | 6.29 MB | $1 \leq \mathrm{n}_{\mathrm{TL}} \leq 21$ |
| $(4128,4096)$ | 8 | $4 \times 512 \mathrm{~B}$ | 9.32 MB | $1 \leq \mathrm{n}_{\mathrm{TL}} \leq 21$ |
| $(4128,4096)$ | 9 | $4 \times 512 \mathrm{~B}$ | 12.66 MB | $1 \leq \mathrm{n}_{\mathrm{TL}} \leq 22$ |

In addition, let us suppose that the coefficients $\ell_{i}$ are stored in each of the four L1 caches and that the syndrome table is placed into the L 3 cache (Table 3). In that case, the processing cores will perform the following operations:

- Core 1

$$
\begin{equation*}
C_{\hat{\mathrm{B}} 1}=\left[C_{1} \cdot \hat{B}_{1}+C_{2} \cdot \hat{B}_{5}+\cdots+C_{k} \cdot \hat{B}_{4 \cdot(k-1)+1}\right]\left(\bmod 2^{b}-1\right)=\sum_{i=1}^{k} C_{i} \cdot \hat{B}_{4 \cdot(i-1)+1}\left(\bmod 2^{b}-1\right) \tag{14}
\end{equation*}
$$

- Core 2

$$
\begin{equation*}
C_{\hat{B} 2}=\left[C_{1} \cdot \hat{B}_{2}+\hat{C}_{2} \cdot \hat{B}_{6}+\cdots+C_{k} \cdot \hat{B}_{4 \cdot(k-1)+2}\right]\left(\bmod 2^{b}-1\right)=\sum_{i=1}^{k} C_{i} \cdot \hat{B}_{4 \cdot(i-1)+2}\left(\bmod 2^{b}-1\right) \tag{15}
\end{equation*}
$$

- Core 3

$$
\begin{equation*}
C_{\hat{\mathrm{B}} 3}=\left[C_{1} \cdot \hat{B}_{3}+C_{2} \cdot \hat{B}_{7}+\cdots+C_{k} \cdot \hat{B}_{4 \cdot(k-1)+3}\right]\left(\bmod 2^{b}-1\right)=\sum_{i=1}^{k} C_{i} \cdot \hat{B}_{4 \cdot(i-1)+3}\left(\bmod 2^{b}-1\right) \tag{16}
\end{equation*}
$$

$$
\begin{align*}
& \text { - Core 4 } \\
& C_{\hat{B} 4}=\left[C_{1} \cdot \hat{B}_{4}+C_{2} \cdot \hat{B}_{8}+\cdots+C_{k} \cdot \hat{B}_{4 \cdot(k-1)+4}\right]\left(\bmod 2^{b}-1\right)=\sum_{i=1}^{k} C_{i} \cdot \hat{B}_{4 \cdot(i-1)+4}\left(\bmod 2^{b}-1\right) \tag{17}
\end{align*}
$$

If we add to this $K / 128$ shift operations ( $K$ - the number of data bits) we easily calculate that each processing core requires $\mathrm{T}_{1}=8 \cdot k+K / 128-1$ clock cycles ( $k$ accesses to the L1 cache, $k$ integer multiplications, $k-1$ integer additions and $K / 128$ shift operations) to compute the value of the check-byte $C_{\hat{\mathrm{B}} \mathrm{P}}(\mathrm{P}=1,2,3,4)$. After finishing this task, each core will take $\mathrm{T}_{2}=2$ clock cycles ( 1 integer subtraction and 1 modulo reduction) to perform the following operations:

- Core 1
$S_{1}=\left[C_{\hat{\mathrm{B}} 1}-\hat{C}_{\mathrm{B} 1}\right]\left(\bmod 2^{32}-1\right)$
- Core 2

$$
\begin{equation*}
S_{2}=\left[C_{\hat{\mathrm{B}} 2}-\hat{C}_{\mathrm{B} 2}\right]\left(\bmod 2^{32}-1\right) \tag{19}
\end{equation*}
$$

- Core 3

$$
\begin{equation*}
S_{3}=\left[C_{\hat{\mathrm{B}} 3}-\hat{C}_{\mathrm{B} 3}\right]\left(\bmod 2^{32}-1\right) \tag{20}
\end{equation*}
$$

- Core 4
$S_{4}=\left[C_{\hat{B} 4}-\hat{C}_{B 4}\right]\left(\bmod 2^{32}-1\right)$
As explained in Section 2, if the data are received in error $(S \neq 0)$, the decoder will additionally perform $n_{\mathrm{TL}}$ table lookups, $n_{\mathrm{TL}}$ comparisons, 1 integer addition and 1 modulo reduction. In our case, four such operations will be executed in parallel in $\mathrm{T}_{3}=29 \cdot n_{\text {TV }}+2$ clock cycles. Consequently, if we sum up all processing times, we come to the conclusion that the processor requires

$$
\begin{equation*}
\mathrm{T}_{\text {total }}=\mathrm{T}_{1}+\mathrm{T}_{2}+\mathrm{T}_{3}=8 \cdot k+K / 128+29 \cdot n_{\mathrm{TL}}+3 \tag{22}
\end{equation*}
$$

clock cycles to process $4 \cdot K$ data bits, i.e. one second to decode

$$
\begin{equation*}
G=\frac{C_{\mathrm{R}}}{\mathrm{~T}_{\text {total }} /(4 \cdot K)}=\frac{\left(3.5 \cdot 10^{9}\right) \cdot 4 \cdot K}{8 \cdot k+K / 128+29 \cdot n_{\mathrm{TL}}+3} \tag{23}
\end{equation*}
$$

data bits. By substituting the values of $K, k$ and $n_{\mathrm{TL}}$ in (23), we obtain that $G_{\min }=16.93 \mathrm{Gbps}$ and $G_{\max }=34.38 \mathrm{Gbps}$. In other words, all codes from Table 4 have the potential to be used in 10G networks (e.g. 10G PONs) [1]. In addition, from Table 4 we see that the codes with code rate 0.9922 have theoretical throughputs above 33 Gbps . Thus, they could be candidates for use in ONWOAs operating at 32 Gbips (e.g. 32G Fibre Channel network) [1]. Finally, from (14)-(21) it is evident that the analyzed codes (Table 4) can correct burst/random asymmetric errors affecting four adjacent 32-bit bytes. This feature makes them more attractive for potential use, since in practice channel errors may corrupt two adjacent bytes [4], [5], [6], [7].

Table 4. Theoretical Decoding Throughputs for Some Four-Byte Interleaved Codes.

| Four-Byte Interleaved <br> $\left(\mathrm{B}_{l / 32} \mathrm{AEC} / \mathrm{R}_{3} \mathrm{AEC}\right)_{32}$ Code | $l$ | Code <br> Rate | Decoding <br> Throughput |
| :---: | :---: | :---: | :---: |
| $(1056,1024)$ | 8 | 0.9697 | 16.93 Gbps |
| $(1056,1024)$ | 9 | 0.9697 | 16.93 Gbps |
| $(2080,2048)$ | 8 | 0.9846 | 25.81 Gbps |
| $(2080,2048)$ | 9 | 0.9846 | 25.15 Gbps |
| $(4128,4096)$ | 8 | 0.9922 | 34.38 Gbps |
| $(4128,4096)$ | 9 | 0.9922 | 33.79 Gbps |

## 4. Comparison with Existing Codes of Similar Properties

In Section 1 we listed several codes capable of correcting multiple asymmetric errors within a $b$-bit byte. Among them, the most interesting are codes presented in [10] and [13]. These codes have similar error correction properties as the proposed codes, and hence, they will be compared to each other.

At the outset, let us focus on the parameters of all codes. According to [10], the codes correcting single $b$-bit byte asymmetric errors (the $S_{b} A E C$ codes) have $b+\log _{2}$ (k) check bits, where $k<2^{b-1}$. This means that the $\mathrm{S}_{16} \mathrm{AEC}$ codes require up to 23 check-bits to protect data words of length $K \leq 2048$ bits. On the other hand, although the presented codes always have $b$ check bits, they cannot be constructed when $l=8, t=3$ and $b=16$. Hence, to protect data words of length $K \leq 2048$ bits, one must use integer $\left(\mathrm{B}_{8} \mathrm{AEC} / \mathrm{R}_{3} \mathrm{AEC}\right)_{b}$ codes that have 32 check-bits. The same applies to codes correcting $t$ asymmetric errors within a $b$-bit [13]. For the parameters $t=3$ and $b=16$, these codes can protect data words of length up to 224 bits. However, for the parameters $t=3$ and $b=32$ they can protect more than 2048 bits.

As far as data processing is concerned, the codes from [10] are significantly different from the proposed codes and the codes given in [13]. Namely, besides using integer and LUT operations, these codes also use bit-oriented operations ( $b-1$ binary additions per $b$-bit byte [10]). Because of this, they are not suited for implementation on modern processors. On the other hand, in Section 3 we have seen that the proposed codes are very suitable for software implementation. The same holds for the codes presented in [13]. The only difference between these two codes is that codes from [13] are less demanding in terms of memory needs. More precisely, for data words of length $K \leq 2048$ bits they require up to 3.17 MB of memory. In contrast to them, the proposed codes demand at most 6.29 MB of memory (Table 5).

Table 5. Comparison of the Proposed Codes with Existing Codes of Similar Properties.

| Main <br> characteristics | Proposed codes | Codes from [13] | Codes from [10] |
| :---: | :---: | :---: | :---: |
| Error correction <br> capabilities | Correction of burst and <br> random asymmetric <br> errors within a $b$-bit byte | Correction of random <br> asymmetric errors within <br> a $b$-bit byte | Correction of any <br> asymmetric error within <br> a $b$-bit byte |
| Maximum number <br> of data bytes | Not specified <br> (depends on the results <br> of a computer search) | Not specified <br> (depends on the results <br> of a computer search) | The largest prime <br> less than $2^{k}$ |
| Number <br> of check-bits | $b$ | $b$ | $b+\log _{2}(k)$ |
| Processing <br> of data bits | Integer and LUT <br> operations | Integer and LUT <br> operations | Integer, LUT and <br> bit-oriented operations |
| Size of the <br> syndrome table <br> when $K \leq 2048$ bits | $\leq 6.29 \mathrm{MB}$ | $\leq 3.17 \mathrm{MB}$ | $\leq 64 \mathrm{~B}$ |

Finally, it must be mentioned that the proposed codes provide the same level of reliability as $\mathrm{S}_{b}$ AEC codes. Namely, although they cannot correct any asymmetric error within a $b$-bit byte, they are sufficiently powerful to correct almost all channel errors. Such a conclusion is indirectly supported by experimental results reported in [4], [5], [6], [7]. On the other hand, the codes from [13] are unable to correct burst asymmetric errors affecting four or more bits. Because of this, they cannot provide high throughput and reliability simultaneously.

## 5. Conclusion

In this paper we presented a class of codes suitable for use in optical networks without optical amplifiers. We have shown that these codes have two important characteristics: first, they can correct burst and random asymmetric errors confined to a $b$-bit byte, and second, they use integer and lookup table operations which make them suitable for software implementation. In addition to this, it was also shown that the proposed codes can be interleaved without delay and without using any additional hardware. Thanks to this fact, it is possible to construct simple codes capable of correcting multiple asymmetric errors affecting several consecutive bytes.
